ABSTRACT

This paper discusses the role of clay selection and preparation in the production of wheel-made pottery in Early Iron Age southern Iberia. The first systematic use of potter's wheels in the production of Early Iron Age ceramics in southern Iberia corresponds to the establishment of pottery workshops associated with Phoenician trade colonies, dating to the period between the end of the 10th and 7th century BCE. There are still many gaps in our understanding of how technological knowledge was transmitted between the Phoenician workshops and 'indigenous' communities that adopted the potter's wheel. This paper draws upon a growing body of archaeometric and ceramic technological research to consider clay selection strategies in these new workshops. Secondly, this paper will consider the role of ceramic raw materials in the development of new 'hybrid' ceramic forms, particularly grey-ware. It will hereby provide theoretical considerations surrounding the significance of material cultural hybridity in answering questions raised by postcolonial archaeologists about identity, cultural transmission and hybridisation in the context of the Phoenician colonial system.

1. Introduction

In the Iberian Peninsula, the first millennium BCE is a period of socio-economic and cultural transformations, which culminated in the development of proto-urban lifeways (Almagro Gorbea, 2014). Widespread changes took place in the organisation of food production and consumption, religious practices, pottery technology and metallurgy. Fundamental to the changes taking place here were the expansion of Phoenician long-distance trade networks, which facilitated the spread of people and technological innovations across the Mediterranean (e.g., Manning, 2018, p.38). In the Iberian Peninsula, Phoenician groups settled in trade colonies on the southern coastline in the 9th century BCE, utilising rural hinterlands for farming and extracting Mineral ores from the interior mountain ranges (Aubert Semmler, 2008; Dietler and López-Ruiz, 2009). The processes of dissemination of elements

from a Mediterranean *koine* developed into the eclectic "orientalising" material culture styles of the southern Iberian Iron Age (Celestino Pérez and López-Ruiz, 2016).

In and around these Phoenician colonies, workshops appeared that utilised the potter's wheel and double-chambered updraught kilns to produce vast quantities of luxury tableware as well as containers for trade goods (Mielke and Torres Ortiz, 2012; Mielke, 2015). In the centuries that followed, the production of wheel-made pottery expanded across the Iberian Peninsula, outside of context of the Phoenician colonial system (Ramón Torres *et al.*, 2007; Delgado Hervás, 2011; García Vargas and García Fernández, 2012; Fernández Maroto, 2013; Jiménez Avila, 2013; Mielke and Torres Ortiz, 2012; Sáez Romero *et al.*, 2021). Despite strong evidence for the growing production and use of wheel-made pottery outside of the Phoenician colonies, particularly after the 7th century BCE (Coll Conesa, 2000), there are still many gaps in our knowledge of the process by which this workshop mode of production developed, how it

*Corresponding author. E-mail: Beatrijs.de.Groot@ed.ac.uk

spread and how its adoption affected existing craft traditions in the Iberian Peninsula.¹

This paper focuses on a specific area of the *chaîne opératoire* of early wheel-made pottery; the selection and preparation of clays, in order to address questions surrounding the development of knowledge about suitable clay and temper recipes for the production of wheel-made pottery. Recent research has provided detailed insights into the production process, or *chaîne opératoire*, of ceramics produced in the Phoenician-tradition workshops (Sáez Romero *et al.*, 2021), evidence which is important for reconstructing the spread of technological information relating to ceramic production across southern Iberia. By comparing data from a growing body of archaeometric research, this paper draws out some general conclusions surrounding the way in which the new pottery workshops built upon, or replaced, traditional knowledge about clay recipes. Particular attention will be paid to the premise, informed by ethnoarchaeological literature, that clay selection and preparation are often a cultural “choice”, rather than an economic or environmentally determined solution. This paper addresses the different factors that might influence clay selection strategies for the production of wheel-made pottery in the context of Iron Age southern Iberia, investigating the opposition between economic and cultural preferences.

To address the above aims, this paper also integrates information about the procurement and preparation of ceramic raw materials into broader philosophical questions surrounding the adoption and rejection of new technologies in Iron Age Iberia. In order to do so it focuses on the development of grey-ware, a class of ceramics that might have developed as a “hybrid” form, imitating hand-made “indigenous” pottery but produced on the potter’s wheel, a technology associated with the Phoenicians. The significance of this type of material is analysed by focusing on evidence for the origin of its ceramic raw materials to understand the mixing of technological knowledge and visual style more fully.

I take the regions of southern Iberia near the Phoenician colonies as my primary case-study because “orientalising” material culture and technology has been strongly influential in this area (omitting Extremadura due to a lack of published archaeometric studies on early wheel-made pottery in this region). This includes the “Tartessian” area, the area of present-day Andalucía, as well as Southern Portugal and Lisbon. The time-period discussed is restricted to the first appearance of Phoenician settlements to the period immediately after the so-called “crisis” in the mid-6th century BCE.

2. Clay selection and preparation; cultural or economic choice?

With the growing importance of post-processual frameworks in archaeology, the development of archaeological thought about the use of raw materials has shifted from a focus on functional properties to culturally informed, transmitted knowledge. Instead of striving for a “best way” in the development of technological practices, research into the *chaîne opératoire* of ceramic production demonstrates that there are numerous equivalent methods to produce ceramics (*e.g.*, Dobres, 1999; Roux, 2019) and that such variation can reflect the technological styles (*e.g.*, Lechtman, 1977) of different social groups. Technological variation can therefore be used to explore questions of cultural transmission and agency (*e.g.*, Pauketat, 2001).

In the context of raw material selection and preparation, the earliest steps in the *chaîne opératoire* of ceramic production, ethnographic studies demonstrate that technological practices might not be deliberately selected, as if choosing the appropriate tool or practice for the task at hand “from a catalogue” (Gosselain, 1992). Instead, the composition of ceramic pastes can reflect the preferences and material knowledge of potters, which are shaped by socially-transmitted conventions (*e.g.*, Gosselain, 1992; Livingstone Smith, 2000; Pauketat, 2001). Spatio-temporal patterns in the similarity of clay recipes can therefore provide insights into the strategies of – and relationships between – contemporary potting traditions, as well as informing a discussion on the long-term development of material knowledge.

Although socially-transmitted information in theory provides an important determining factor in the selection of clay and temper, potters establishing the first workshops in the Iberian Peninsula will have had to take a number of factors into account. Such workshops will have been part of the Phoenician commercial economy, in which ceramic production ran parallel to other industries to facilitate the production and long-distance trade of goods (see below). The choice of clay and temper formed part of a wide set of demands, such as the proximity of pottery workshops to transport routes and food production sites, which will have affected the choice of raw material source next to personal preference or social conventions. Furthermore, wheel-thrown pottery is generally produced from clay with fine-grained non-plastic inclusions to avoid abrasion of the potter’s hands (Rice, 2015, p.143) or marring and tearing of the pot surface (Sinopoli, 1991, p.101), suggesting that the properties of clays deserve attention in explaining selection.

As such, it is important to assess how innovations act as “systems” of related technological choices, raw materials, logistics and economic contexts (*e.g.*, Sillar and Tite, 2000). By providing empirical evidence of continuity or the changes in raw material selection co-occurring with the introduction of the potter’s wheel, mineralogical and archaeometric studies can contribute to understanding the workings of changes in such technological systems. By focussing on the materials from which ceramics were made, it is possible to gain

¹ The complexity of the processes of interaction underpinning the spread of potter’s wheels is emphasised by the suggestion that rotational devices were used from the Final Bronze Age onwards in Central Iberia at El Castro de Cogotas during the 9th to 7th century BCE (Padilla-Fernández, 2019).

insights into processes of communication of environmental knowledge and/or experimentation with new clay recipes and the cultural construction and use of the landscape (e.g., Albero Santacreu, 2017), particularly concerning the location of suitable clay sources and clay procurement strategies. Below I will integrate such information in a broader discussion on the development and spread of pottery production in Early Iron Age southern Iberia.

3. Background: the economics of Phoenician pottery production

In order to investigate the organisation of ceramic production in western Phoenician communities it is informative to consider the role of ceramic production in the wider Phoenician colonial system. Although the relation between the adoption of potter's wheels and mass-production is rarely straightforward (Roux and Courty, 1998; Baldi and Roux, 2016; Choleva, 2020)², in the western Mediterranean

the introduction of this technology corresponds closely to the intensification of ceramic production for long-distance trade. The production of storage containers and tableware in this region was initially part of the commercial strategy of Phoenician colonies, whose economy focussed on the maritime trade of agricultural surplus and luxury goods. Phoenician pottery of local manufacture was found at Huelva (Figure 1) in layers dating to at least 900 BCE (Millán *et al.*, 1990; Nijboer and van der Plicht, 2006; Delgado Hervás, 2011, pp.11–12; González de Canales *et al.*, 2017). Evidence for the local production of Phoenician-type wheel-made pottery indicates that eastern Mediterranean(-trained) potters were quick to instate a local pottery industry after settlement in the Iberian Peninsula (Millán *et al.*, 1990), which will have involved the use of double-chambered updraught kilns as well as the use of low potter's wheels or stick wheels (e.g., Jiménez Avila, 2013). The earliest excavated ceramic workshops in Phoenician centres at Málaga and Toscanos date to the 7th century BCE (Curià Barnès *et al.*,

² Roux and Courty (1998) distinguish the different shaping methods the potter's wheel affords, providing valuable insights into the utilisation of Rotational Kinetic Energy (RKE) next to combinations of hand-shaping and rotation. Although comprehensive studies of the shaping methods employed in the production of Phoenician pottery in the Iberian Peninsula

are rare, some evidence demonstrates that such pottery was produced through different shaping technologies including wheel-throwing and wheel-coiling (Dorado Alejos, 2019). Hand-shaping methods prevailed in the Iberian Peninsula during the Late Bronze Age, with pinching, coiling and slab-building recorded for assemblages across the Iberian South-East (e.g., Dorado Alejos, 2019).

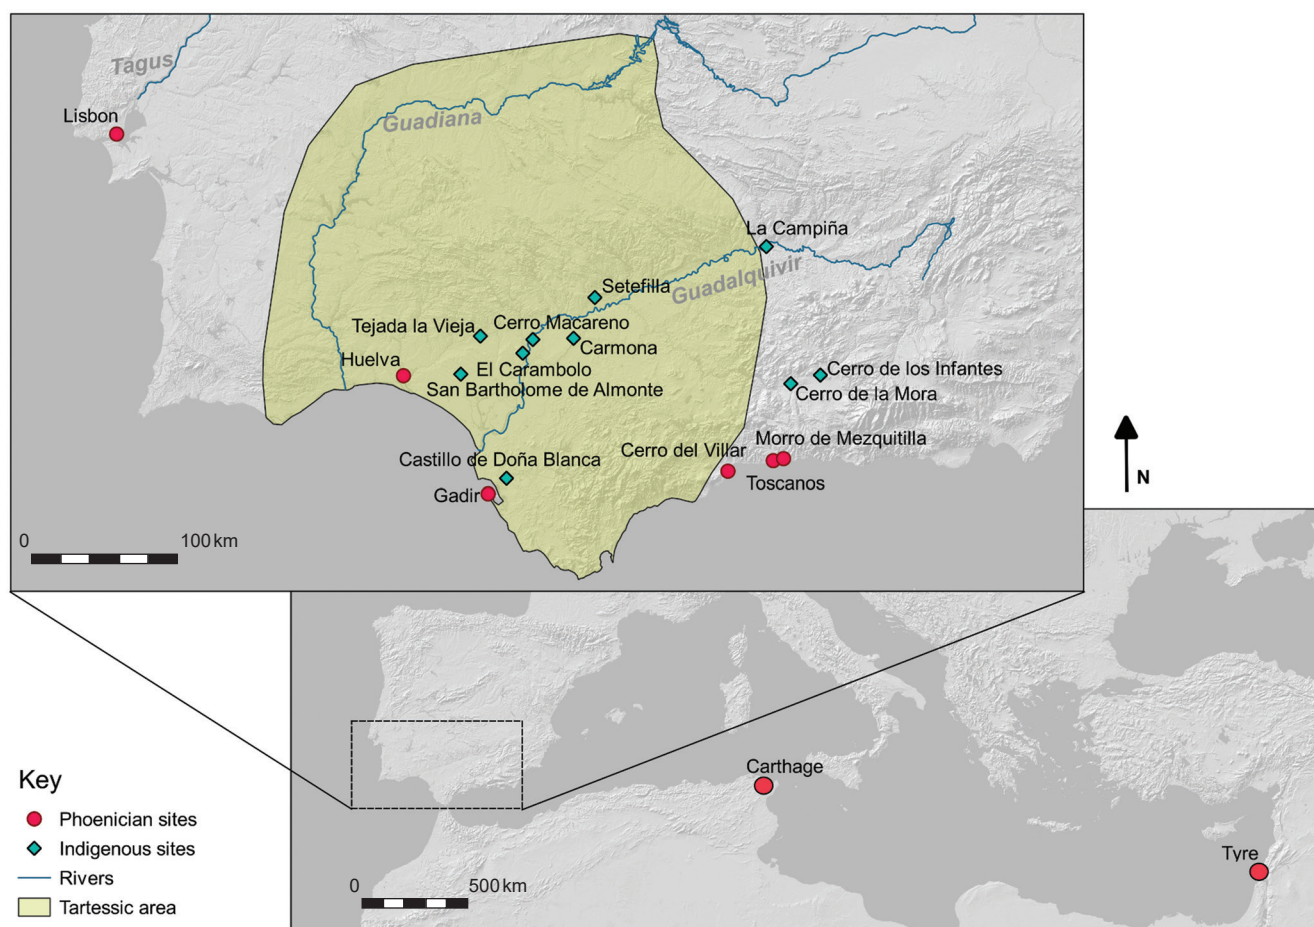

Figure 1. Map of sites with published archaeometric data on Early Iron Age pottery. The shaded area marks the outline of the area of influence of Tartessos (after Celestino Pérez and López-Ruiz, 2016, p.175).

2000; Arancibia-Román and Escalante Aguilar, 2006; García Vargas and García Fernández, 2012; Mielke and Torres Ortiz, 2012, p.279). Evidence of ceramic manufacture in and nearby other Phoenician sites dating to the same period also derives from the distribution of ceramic prisms, which were used to separate pottery during firing within the kiln and are highly diagnostic (Delgado Hervás, 2011; Gutiérrez López *et al.*, 2013). During this period, next to the production of Phoenician-type ceramics, there is also evidence for the local production of ceramics of Greek typology at Huelva (González de Canales *et al.*, 2018) as well as the development of “hybrid” ceramic forms such as grey-ware (explored further below), pointing to the heterogeneous influences affecting wheel-made pottery production in southern Iberia.

Phoenician workshops such as Cerro del Villar produced symmetrical and standardised storage vessels (amphorae, pithoi, globular pots and bottles), tableware (plates, carinated bowls, dishes, jars and cups) and vessels destined for other uses (pots, urns, tripods) (Curià Barnès *et al.*, 2000, p.1475). Archaeometric studies confirm that such ceramics circulated widely in the western Mediterranean (Behrendt and Mielke, 2011; Miguel Gascón *et al.*, 2015) as well as reaching more distant places in the eastern Mediterranean (Fantuzzi *et al.*, 2020). One of the largest and most comprehensive of such studies on the provenance of early wheel-made pottery in the Iberian Peninsula is the Instrumental Neutron Activation Analysis (INAA) research conducted by Sonja Behrendt (Behrendt and Mielke, 2011). Chemical signatures from 224 Phoenician wheel-made ceramic samples were obtained from vessels deriving from nineteen Early Iron Age Phoenician sites in the southern half of the Iberian Peninsula and northern Morocco. The results show that wheel-made pottery circulated around four main production centres associated with workshops in Phoenician settlements (Behrendt and Mielke, 2011, p.193). Phoenician ceramics from production centres located around the Straits of Gibraltar, Sicily and Carthage appear in Early Iron Age contexts in north-eastern Iberia (Miguel Gascón *et al.*, 2015) and the Atlantic coast of Iberia (González-Ruibal, 2004; de Sousa, 2019), suggesting that the Phoenician colonies controlled trade with indigenous Iberian communities as intermediaries through a so-called cabotage system (Rafel Fontanals, 2012).

The potter's wheel was an integral part of the process of containerisation and wider economic opportunities regarding the speed and quantity of production, (Bevan, 2014, p.392) standardisation and the generation/exploitation of new markets. The economic character of early workshops employing the potter's wheel is reflected by the location of pottery workshops, which overlapped with that of the production of agricultural trade goods (Bernal Casasola and Sáez Romero, 2003). Industrial landscapes marked by the convergence of pottery production and salted-fish processing for trade seem to have emerged soon after the emergence of Phoenician settlements and flourished in the Punic period (c. after 550 BCE) (Sáez Romero, 2008; Carretero, 2007; Sáez Romero, 2014). Through connecting

such industrial landscapes to the wider Mediterranean, the exchange in foodstuffs and luxury tableware offered opportunities for generating wealth. The development and prevalence of “orientalising” objects in the Tartessian region (Figure 1) of the Iberian south demonstrates how, next to the inhabitants of the Phoenician colonies, segments of the broader population exploited such opportunities (Delgado Hervás, 2013).

3.1 The inland spread of pottery workshops

During the 7th century BCE, workshops with Phoenician-type kilns appear in the southern half of the Iberian Peninsula, in “indigenous” settlements such as Cerro de los Infantes (Mendoza *et al.*, 1981; Mielke, 2015; García Vargas and García Fernández, 2012), Cerro de la Mora (Carrasco *et al.*, 1985) and La Campiña (Molinos *et al.*, 1994) (see also Sáez Romero *et al.*, 2004; García Vargas and García Fernández, 2012). Workshop-based production of wheel-made amphorae and fine ware is also attested at a number of different indigenous sites as indicated by archaeometric studies, as will be discussed further below. Such production centres, located outside of the immediate surroundings of the Phoenician colonies, demonstrate that local groups began to participate in the production of ceramics for regional and interregional trade. This process intensifies after the 6th century BCE “crisis” (Escacena Carrasco, 1993), a period in which the Phoenician colonial system declined (*e.g.* Torres Ortiz, 2014, p.275). Petrographic and chemical analysis of amphorae dating to the 6th–2nd centuries BCE demonstrates that new workshops, located in the Guadalquivir Valley and the Tagus and Sado Valleys of Portugal, and the Iberian East coast, developed, gaining access to the commercial networks that were originally controlled by the Phoenician colonies (González Prats and Pina Gosálbez, 1983; Moreno Megías *et al.*, 2020). This has provided evidence contributing to existing discussions about the relationship between coastal and inland economic systems during this period. After the 6th c. BCE, amphorae were used for the transport of wine as indicated by residue analysis (Petit-Domínguez *et al.*, 2003), and a range of other products such as olive oil, fish by-products, honey, meat preserves and milk by-products (Carretero *et al.*, 2008; García Fernández *et al.*, 2016). During this period, we also find the development of ceramic industries associated with the Central and Northern Iberian oppida, forming a new and highly decorative style of locally-produced, wheel-made ceramics (Lorrio, 2014).

This general overview suggests that commerce was an important driver for the initial spread of the potter's wheel in southern Iberia. The production of ceramic transport containers and luxury commodities at different centres on the Iberian south coast indicate that a significant level of standardisation existed, allowing these different centres to produce in-demand commodities for local and distant markets. The next section will examine if such standardisation is also reflected in choices potters made in selecting clay and temper.

4. Clay provenance and preparation in Early Iron Age southern Iberia

A growing body of archaeometric work has provided evidence for petrographic and chemical groupings in Phoenician pottery from the western Mediterranean (e.g., Arribas *et al.*, 1989; Millán *et al.*, 1990; Amadori and Fabbri, 1998; Pringle, 1998; Cardell *et al.*, 1999; Edreira *et al.*, 2001; Ruiz *et al.*, 2006; Cau Ontiveros, 2007; Cau Ontiveros *et al.*, 2010; Behrendt and Mielke, 2011; Miguel Gascón *et al.*, 2015; Johnston, 2015; Ferreira *et al.*, 2020). Such studies provide data concerning the variability of fabrics and origin of clay sources at individual sites, but they also reveal information on clay procurement and preparation strategies characterising western Phoenician ceramic production and how this compares to such technological habits in indigenous contexts. The review of a selection of this archaeometric research below provides an initial characterisation of the technological choices made by potters utilising potter's wheels in Early Iron Age southern Iberia (both in indigenous and Phoenician contexts). The aim of this is to provide a discussion as to whether these can be understood as part of a broader “technological style” or are informed by economic choices and environmental variation.

4.1 Clay procurement

A starting point for understanding clay selection preferences in the western Phoenician colonies is to compare the nature of the ceramic fabrics from different Phoenician and “indigenous” ceramic workshops and consider variation in the mechanical properties of ceramic raw materials. In order to situate Phoenician ceramic production in Iberia, it is useful to characterise clay procurement and preparation habits of other Phoenician settlements. For example, Phoenician ceramics from the necropolis of Tyre-al Bass, dating to 850–550 BCE, were produced from highly calcareous pastes (Miguel Gascón and Buxeda i Garrigós, 2013), while calcareous clays tempered with crushed calcite or sand were used in the production of wheel-made pottery at Carthage (Miguel Gascón *et al.*, 2015). Phoenician pottery from Sardinia, instead, is often tempered with grog (Miguel Gascón *et al.*, 2015), demonstrating that variation exists between clay preparation strategies in different Phoenician contexts. In the Iberian Peninsula, however, a preference for using calcareous clays or clays with a high calcite content in the production of Phoenician-type ceramics seems likely (Table 1). Calcareous clays were used in the production of wheel-made Phoenician pottery from Castillo de Doña Blanca, near the Phoenician colony of Gadir (Cau Ontiveros, 2007; Johnston, 2015; Fantuzzi *et al.*, 2020, p.6) as well as at Huelva and São Jorge Castle in Lisbon (Ferreira *et al.*, 2020). At the indigenous site of Cerro Macareno, wheel-made pottery is produced from calcareous clays, contrasting with handmade pottery, which is produced from metamorphic clays (González-Vilchez *et al.*, 1982). Also at Setefilla (Bartkowiak and Krueger, 2015; Krueger *et al.*, 2018; Krueger *et al.*, 2021), there seems to have been a preference

for using calcareous clay in the production of wheel-thrown pottery, although ferruginous clays were also often utilised (Krueger *et al.*, 2018).

The advantageous properties of calcareous clays are that such clays sinter at lower temperatures, allowing for a less tight control over firing to obtain a suitable level of strength (Tite and Maniatis, 1975). Other mechanical properties of clays with a high calcite content include the way in which calcium affects the clay-water system, improving their toughness and workability (Hoard *et al.*, 1995, p.265, Müller *et al.*, 2014), properties that are useful for ensuring the structural integrity of vessels during shaping or throwing on the wheel. Whether the selection of clays was determined by such functional advantages is debatable, particularly because many different factors can contribute to the choice of clays (see Discussion). Furthermore, many other workshops utilised non-calcareous clays from nearby deposits for the production of wheel-made pottery (Fantuzzi *et al.*, 2020, Amadori *et al.*, 2017, Amadori and Fabbri, 1998, Ferreira *et al.*, 2020, Ferreira *et al.*, 2018). For example, late 8th century and 7th century BCE wheel-made pottery from Toscanos were produced using metamorphic clays while a second, calcareous fabric, corresponds to imports from Carthage (Amadori *et al.*, 2017). Evidence for particular clay procurement strategies other than an opportunistic use of locally available resources is therefore currently limited, but future consideration of the mechanical differences in pottery clays for producing wheel-made pottery can be informative about the observed distinction between the raw materials used for the production of hand-made and wheel-made pottery.

4.2 Clay preparation

Ceramic petrography can provide insights into the use of temper, indicated by the angularity of inclusions, grain-size distribution (which should be bimodal if crushed rocks or sand is added as temper), and a difference in the minerals in coarse and fine fraction (Quinn, 2013). Nevertheless, it can often be challenging to confirm if mineral inclusions were added as temper or whether such inclusions were naturally present in the clay matrix. The reviewed literature demonstrates that we have limited conclusive evidence for the use of temper in the production of early wheel-made pottery in the Phoenician colonies. Non-plastics in the ceramic fabrics of wheel-made pottery often reflect minerals that could be present in clays naturally. The use of crushed calcite is suggested at a number of sites that are part of Behrendt and Mielke's (2011) study, although the authors are not explicit about the question of whether materials are added as temper (Behrendt and Mielke, 2011, pp.198–223). At Castilla de Doña Blanca there is one quartz-tempered fabric group (Johnston, 2015, p.253) among the wheel-made samples, but in other contexts the literature is inconclusive.

Wheel-made ceramics produced in indigenous contexts more often contain temper. For example, the use of mineral tempers seems to have been common in the production of Punic-Turdetanian amphorae during the 6th–2nd centuries

Table 1. Summary of archaeometric studies (TSCP: Thin-Section Ceramic Petrography, XRF: X-Ray Fluorescence, XRD: X-Ray Diffraction).

Production location	Approx. period (centuries BCE)	Reference	Total nr of analysed samples	Method	Clay composition in wheel-made pottery	Evidence of tempering wheel-made	Inclusions wheel-made	Different clay-sources hand-made vs wheel-made pottery

BCE (Moreno Megías *et al.*, 2020, pp.6–10). At Setefilla, we find the presence of vegetal temper in wheel-made pottery, which also occurs in some hand-made vessels (Krueger *et al.*, 2021). Based on the reviewed studies it therefore appears that there is little evidence for a set clay recipe in the production of early Iron Age wheel-made pottery in southern Iberia. However, future systematic and targeted comparative studies might be able to draw out regional or local similarities more clearly.

Instead of adding minerals as temper, it is likely that, instead, potters often removed larger minerals and other impurities. Fantuzzi *et al.*'s (2020) study of amphorae from different production centres on the southern Iberian coastline demonstrates that clay samples from around Phoenician settlements often contain larger mineral fragments than the clay fabrics analysed, suggesting that such clays might not have been used in a raw state, but rather were processed prior to shaping. A range of clay preparation methods can be used to purify clays, such as drying the clay, crushing, grinding and winnowing or sieving it in a dry state, or levigating, in which clay is mixed with water to separate coarser inclusions from the clay matrix (Rice, 2015, p.133). To explore such methods and how they might have been utilised in Early Iron Age Iberia, some experimental studies have been conducted (see Krueger *et al.*, 2018, Sáez Romero *et al.*, 2021).

Continuity in the use of clay sources by indigenous groups adopting the potter's wheel would provide important evidence for the persistence or sharing of technological knowledge between potters with different modes of production. Below I will consider this topic in more detail and discuss its implications for understanding questions surrounding identity and processes of hybridisation in the southern Iberian Early Iron Age.

5. Postcolonial perspectives and material hybridity

Evidence for the persistence and/or abandonment of deep-rooted technological knowledge can contribute to examining questions of identity in the context of the Phoenician colonisation of the Iberian Peninsula and particularly the power dynamics between indigenous and Phoenician settlements. Studies of ancient forms of colonialism in the Mediterranean address the contribution of the “colonised” to processes of culture change under the banner of postcolonial archaeology (Gosden, 2004; Tronchetti and Van Dommelen, 2005; Hodos, 2009; Van Dommelen, 2011). Under the influence of such research, it is often considered that processes of cultural interaction taking place in eastern Mediterranean colonies in the western Mediterranean resemble a “Middle Ground” (Gosden, 2004) in which people and cultures interact and mix. Such work, in part, draws upon a set of concepts put forward by Homi Bhabha (1994) to describe the political dimensions of interaction and identification in postcolonial situations (see also Stockhammer, 2012, p.46). Bhabha utilised the concept of “hybridity” to describe the “in-betweenness” of culture, and “Third Space” as the arena

where the interactions that constitute new identities take place, describing a tension between “received” tradition and its re-evaluation in the light of authorised power and privilege (Bhabha, 1994, p.3). Such concepts have been employed by postcolonial archaeologists to recognise that power-relationships in colonial systems are not wholly asymmetrical and that identities of both “coloniser” and “colonised” are complex and in flux, constituted by people drawing upon multiple resources, ideas and practices. This is in contrast to more simplistic traditional accounts that dichotomously see the “colonised” as passive receivers of a “dominant” coloniser's material culture (Hodos, 2010). In the absence of first-hand accounts of processes of hybridisation and interaction in ancient societies, archaeologists have suggested that the terminologies of postcolonial theory of Bhabha and others can be used to describe relationships within ancient forms of colonialism, utilising artifacts and material culture as evidence of the transformed and novel identities that emerged in the Iron Age Mediterranean.

In the context of the Iberian Peninsula, for example, we find references to “hybrid” grey-ware, ceramics produced on the potter's wheel but with typological elements that are thought to originate in pre-colonial, Late Bronze Age ceramic traditions (Roos, 1982; Caro Bellido, 1989; Lorrio, 1989; Mancebo *et al.*, 1992; Maass-Lindemann, 2000; Sanna, 2009). In particular, grey-ware was fired in reducing atmospheres which is uncommon in Phoenician ceramic production but is standard in Late Bronze Age ceramic production in southern Iberia (see also Dorado Alejos, 2019). This characteristic of grey-ware is considered by some as an intentional strategy to appeal to a new aesthetic in which indigenous preferences are adopted in Phoenician products to cater for local markets (Vallejo Sánchez, 2016). The process by which such hybrid pottery types developed is, however, still poorly understood partly due to a lack of recent typological studies and evidence from the early stages of Phoenician colonisation. Recent evidence from Castillo de Doña Blanca, which will be discussed below, provides a rare glimpse into the technological choices that underpin the production of grey-ware pottery and will therefore be used as a basis for addressing the relevance of petrographic analysis for addressing questions about material hybridity (Johnston, 2015).

Another issue is that it is not often clear exactly what is meant when the term hybridity is used to describe archaeological phenomena. Discussions are needed to take into consideration the discrepancy between the contexts of production and the context of use of objects, in which the context of production is often governed by culturally transmitted conventions and embodied skills that are for the most part reproduced unconsciously. Furthermore, although material culture appears hybrid to the eyes of archaeologists, it might not have been perceived in the same way in the past. Lastly, Bhabha's (1994) utilisation of the term addresses the political dimensions of processes of hybridisation, which translate poorly to the distant past. The remainder of this article, therefore, assesses the theoretical approaches to ceramic technology and discusses how

notions of technological change are conflated with theories of hybridisation in the Phoenician colonial system.

5.1 The development of “hybrid” ceramic technologies

A petrographic and chemical study of ceramic production in the Bay of Cádiz provides insights into the coexistence of different pottery technologies in the Early Iron Age (Johnston, 2015). This has shown that separate technological traditions, relating to the production of Phoenician pottery on the one hand, and to the production of hand-made burnished ware on the other, co-existed between c. 750–550 BCE (Johnston, 2015). Phoenician pottery was produced from marl-rich clays from nearby the Phoenician settlement at Gadir. Late Bronze Age and Early Iron Age hand-made pottery, instead, was produced from clays from two distinct sources, tempered with dolerite or grog (Johnston, 2015, p.332). This shows that distinct clay selection and preparation methods corresponded to distinct fashioning methods. Johnston's (2015) research demonstrates that one of the clay sources utilised by Late Bronze Age potters is gradually abandoned during the Early Iron Age. This evidence shows that contemporary potting traditions in this region were completely distinct despite their spatial proximity, reflecting persisting technological “polarisation” (e.g., Roux *et al.*, 2017), corresponding to processes of learning and information transmission addressed in sections 2 and 3.

Nevertheless, this study also shows that new forms of ceramics, particularly grey-ware, might have developed in the context of the Phoenician pottery workshop. Grey-ware, although later produced on the potter's wheel, was here initially hand-made. However, instead of corresponding to Late Bronze Age technologies, such ceramics were produced from clays which match the composition of the contemporary wheel-made Phoenician pottery (Johnston, 2015, p.333).

In contrast, in indigenous production centres such as Cerro de los Infantes, there might have been continuity in the use of pre-existing clay sources for the production of grey-ware, given that grey-ware from Morro de Mezquitilla falls into a similar geochemical grouping as Final Bronze Age pottery from this site (Dorado Alejos, 2019, pp.443–444). Also at Setefilla, there is no clear distinction between clay pastes used for the production of hand-made or wheel-made pottery, and vessel shapes originating in local Late Bronze Age and Phoenician pottery traditions are produced using either shaping method (Krueger *et al.*, 2018).

Based on these rare studies, it seems as though the selection of clays for the production of grey-ware reflects broadly the divergence we find in the uses of clay between Phoenician and indigenous production centres. Such evidence suggests that grey-ware developed separately in different technological traditions, a point which will be further explored below.

6. Discussion

This article set out to evaluate the contribution of archaeometric studies to questions of social interaction and

cultural transmission corresponding to the spread of the potter's wheel in the Iberian Peninsula during the Iron Age. Preliminary conclusions that can be drawn from this and areas for future research are discussed below.

The picture that emerges from the growing body of archaeometric and technological studies supports theories about the commercial strategies of Phoenician colonies, utilising locally produced ceramics for trade. Studies into the provenance of Phoenician ceramics demonstrate that the local production of pottery in and nearby the Phoenician colonies commenced rapidly, utilising clays encountered in the surroundings of such sites.

Phoenician ceramic production marks a significant departure from foregoing ceramic technologies, not only in the shaping methods employed (probably utilising stone “pivot and socket” wheels similar to those found at sites in the eastern Mediterranean), but also in the organisation of ceramic production, the labour force involved and the clay sources exploited. Archaeometric evidence from Phoenician and indigenous settlements in the Bay of Cádiz area provides a clear example of this shift by demonstrating that clay procurement and clay preparation strategies of potters utilising traditional hand-shaping methods, and those that worked with the potter's wheel, differed significantly (Johnston, 2015). Notably, evidence of the organisation of ceramic production in indigenous Iberian villages is scarce, and it is broadly assumed that domestic modes of production prevailed. Some scholars have gone as far as to suggest that such hand-made pottery traditions relate to female labour, whilst the introduction of the potter's wheel marks a shift to the production and control of ceramic manufacturing by men (Delgado Hervás and Ferrer, 2007; Padilla Fernández and Dorado Alejos, 2017). The appearance of wheel-thrown pottery alone cannot confirm such shifts in the division of labour, and we should be careful to associate specific classes of objects with specific ethnic or gender groups without substantial evidence.

Furthermore, due to the emphasis of Iron Age research on wheel-made pottery, be it for typochronological purposes or because such ceramics are seen to allude to trade and interaction, the persistence and scale of pottery production outside the workshop is unknown. Research into the chronology of wheel-made and hand-made pottery in the Iberian Peninsula has shown that the production of hand-made pottery persists alongside the production of wheel-made pottery at most sites throughout the first millennium BCE, being more prevalent in northern Iberia (de Groot and Bloxam, 2021). In order to understand the impact of the adoption of the potter's wheel across the Iberian Peninsula, and its effect on local economies and the organisation of labour, it is therefore essential to consider the organisation of the production of hand-made pottery, and how this changes through time. Archaeometric research that compares such contemporary hand-made and wheel-made pottery can provide further insights into the level of technological continuity such hand-made ceramics exhibit.

6.1 Hybridity and the spread of the potter's wheel

Grey-ware provides an interesting glimpse into the development of new forms of material culture in the western Phoenician colonies. Although previous research has highlighted the “hybrid” nature of such ceramics, in the light of difficulties in establishing the nature of the social processes and political intentions underpinning the production of this material culture, “hybridity” (sensu Bhabha) might not be the most useful term to describe these processes (see section 3). It is possible that elements of distinct pottery traditions in the Bay of Cádiz transcended the boundaries of their “polarised” production strategies (see Johnston, 2015 and section 4.3), but, in the case of grey-ware ceramics, it is impossible to be certain which elements are “Phoenician” and which are “indigenous”. As far as the evidence allows, most of the grey-ware’s technological and stylistic characteristics could be ascribed to Phoenician ceramic production, although this changes when its production in “indigenous” workshops is considered. Even if such ceramics developed as hand-made shapes, their later production on the wheel might not indicate a deliberate process of imitation of Late Bronze Age shapes and colour-schemes. Finally, considering the nature of ceramic technology, instead of adhering to fixed practices, it may be under constant negotiation due to the influence of “unpredictable circumstances, surroundings, and mix of participants” (e.g., Pauketat, 2001, p.80, my emphasis). The randomness of such factors suggests that the hybridisation we observe in the wake of ancient forms of colonialism is in fact no different from any other processes of technological change that we can trace in the archaeological record.

A final comment to make is that studies of ancient forms of colonialism and hybridisation are deeply preoccupied with questions of ethnicity. In the context of this research, it is not at all clear who worked in Early Iron Age pottery workshops. The Levantine population in the Iberian Peninsula might have been quite limited, being restricted to a relatively small group of merchant families, rather than a persistent influx of individuals from the eastern Mediterranean. It is telling that ancestry from Central and Eastern Mediterranean individuals only shows up in ancient DNA sequences from the Iberian Peninsula during the Late Iron Age (Olalde *et al.*, 2019, p.3), suggesting that migration into Iberia from these regions was low in the Early Iron Age.

This raises several questions: firstly, who was responsible for controlling Phoenician ceramic production and the trade in goods; and, secondly, did the individuals in control identify as Phoenicians, indigenous, both or neither? Perhaps it is more helpful to speak of the rearrangement of hierarchical structures driven by Phoenician commerce, rather than ascribing ethnic categories to the inhabitants of southern Iberia. Those who controlled the production and flow of goods are likely to have benefitted most from the economic opportunities long-distance networks afforded (e.g., Delgado Hervás, 2013, pp.322–323). Instead, those who provided agricultural labour, worked in mines, and those who worked in pottery workshops, are likely to have experienced the physical impacts of the Early Iron Age economic

transformations. It is therefore tempting to speculate that material culture such as grey-ware is a manifestation of the interactions taking place during the reorganisation of labour. Such processes will have affected the intergenerational transmission of pottery technologies, leading in some cases to their abandonment. In other cases, the development of new production strategies may have facilitated the collaboration between skilled and unskilled craftspeople, leading to new contexts and outcomes of production.

7. Conclusions

This paper has attempted to summarise and compare some initial finding from existing technological studies concerning the uses of ceramic raw materials in the first ceramic workshops in the Iberian Peninsula. This study demonstrated how evidence from archaeometric and ceramic petrographic studies can be integrated into debates surrounding cultural transmission, the development of technological knowledge, and “hybridity”, in the context of the Phoenician colonisation of the Iberian Peninsula. The above interpretations should improve if evidence from future archaeometric studies is discussed comparatively.

Acknowledgements

This research was funded by the author’s Leverhulme Trust-funded Early Career Fellowship project entitled “Economies of innovation: tracing the potter’s wheel in Iron Age southern Europe” (ECF-2019-081). I would like to thank the organisers of the “Archaeological Approaches to the Study of the Potter’s Wheel” conference and two anonymous reviewers for their helpful comments and suggestions. 2021
